Supporting Information

ABSTRACT: In comparison with the popular Ac₄ManNAz applied as cell labels via Cu-free click chemistry, two novel azido mannosamine lipids with C₆ and C₁₂ esters on anomic hydroxyl groups were prepared and encapsulated in a liposome delivery system, which enhanced chemical stabilities and showed good cell-metabolizable labeling efficiency on MDA-MB-231 cells with strong fluorescence after the treatment of DBCO-Cy5 by triazole formation via click chemistry.

Metabolic oligosaccharide engineering of unnatural carbohydrates created by the Bertozzi group has become a powerful tool to introduce chemical receptors onto cell surfaces. Based on the successful employment of modified N-azidoacetyl mannosamine (ManNAz) which can also be metabolized through the sialic acid biosynthetic pathway and incorporated onto cell surface sialoglycoconjugates as normal sialic acids, such biosynthetic precursors of the ManNAz derivative containing an azido group as a chemical probe can be used as metabolic tracers for labeling sialoglycans through different types of click chemistry on the azido group. Since then, the application of click chemistry in vitro and in vivo has been widely applied in the research of cell labeling due to the favorable features, especially on biocompatibility and high specificity with a good reaction rate. This type of cell labeling strategy has been developed as an efficient method to incorporate selectively reactive chemical groups into cell-surface glycoproteins by novel molecular, nanoparticle, and liposomal strategies of delivery systems. Tetraacetyl-N-azidoacetylmannosamine (Ac₄ManNAz, AAM) is one of the most extensively studied metabolic cell-labeling reagents, which can be typically metabolized in the cell through sialic acid biosynthesis to azido sialic acid on the cell membrane and then label the cell through click chemistry after treatment with dibenzocyclooctyne (DBCO)-bearing reagents.

In order to improve the chemical stability and cell labeling efficiency of Ac₄ManNAz (AAM), we prepared derivatives of AAM with different carbon chain length esters at the C-1-OH of Ac₃ManNAzOH for hydrophobic lipids (Scheme 1). Herein, two novel liposomal azido mannosamine lipids loaded with hexanoic (C₆) or dodecanoic (C₁₂) ester tails instead of acetyl (C₂) ester on the anomic hydroxyl group of Ac₃ManNAzOH were designed and prepared to test the cell labeling efficiency via Cu-free click chemistry. To overcome the low water solubility of the lipids with long ester tails (Scheme 2), we took advantage of the liposome system, and all the azido-lipids were encapsulated by the liposome system with good loading efficiencies.

RESULTS AND DISCUSSION

Starting with AAM from the previous work, triacetyl-N-azidoacetylmannosamine lipid (Ac₃ManNAzOH-lipid) was successfully synthesized through selective exposure of the hydroxyl group on the anomic carbon and acylation with varying carbon chain length lipid tails of saturated C₆ or C₁₂ fatty acids in concise routes (Scheme 2). In the assessment of the hydrolytic degradation by HPLC, C₆ and C₁₂ lipids (Figure 1A) showed much more chemical stability than AAM in 37 °C incubation in PBS (Figure S2 in the Supporting Information). Ac₃ManNAzOH lipid-loaded liposomes were continually prepared by the highly efficient process by extrusion of the lipid mixture with 1,2-distearoyl-sn-glycero-3-phosphocholine (DSPC), cholesterol, and 1,2-distearoyl-sn-glycero-3-phosphoethanolamine-N-[amino(polyethylene glycol)-2000] (DSPE-PEG2000, Figure 1B). The prepared Ac₃ManNAzOH lipid-loaded liposomes had effective dia-

ters of around 200 nm as determined by dynamic light scattering (DLS) and sugar loading efficiency of 72% (Figure S3 in the Supporting Information) on the C2 lipid (AAM), 41% (Figure S4 in the Supporting Information) on the C6 lipid, and 50% (Figure S5 in the Supporting Information) on the C12 lipid (Figure 1C). The C2 lipid (AAM) had the highest loading efficiency, which might be associated with its higher water solubility in the four types of lipids (Figure S1 in the Supporting Information), so AAM might not only distribute into the liposome membrane as other hydrophilic lipids but also partially dissolve in the aqueous fluid part of liposome.

Sugar release test of Ac₃ManNAzOH lipid-loaded liposomes by the reverse-titration method of DBCO-Cy3 (Figure S6 in the Supporting Information) indicated that the C2 and C6 lipid-loaded liposomes had the faster release rates, while C12 lipid-loaded liposomes had significantly lower release rates under the same physiological conditions (Figure 1D).

We next tested the cell-labeling efficiency of Ac₃ManNAzOH lipids on MDA-MB-231 breast cancer cells. The cells were incubated with 10 μM Ac₃ManNAzOH lipid-loaded liposomes for 2 or 12 h, and then treated with DBCO-Cy5 independently for another 1 h to detect the expression of the azido groups via Cu-free click chemistry. The cells without liposome treatment were used as a negative control in PBS. Flow cytometry measurements of the Cy5 fluorescence intensity (Figure 2A) showed that all the Ac₃ManNAzOH lipid-loaded liposomes could label MDA-MB-231 cells efficiently in contrast with PBS as the negative control after 12 h incubation. In contrast with the results of the 12 h incubation group, fluorescence intensities after 2 h incubation showed no significant differences between the cells treated with Ac₃ManNAzOH lipid-loaded liposomes and those treated
with PBS. There were also no significant differences in fluorescence intensities between the cells treated with free AAM as the positive control compared with the AAM liposome (Figure 2C), which indicated that the difference between the 2 and 12 h incubation groups was probably due to the time needed for the biosynthesis and metabolic pathway.

Furthermore, the cell labeling results indicated that all the Ac3ManNAzOH lipids could be metabolized onto the cell membrane glycoprotein through sialic acid biosynthesis by SDS-PAGE compared with Coomassie blue staining (Figure 2B). Fluorescence intensity could be observed directly on the SDS-PAGE gel under 365 nm UV because of the highly effective formation of a stable triazole from azido-glycoprotein binding with the fluorescent dye DBCO-Cy5 through click chemistry.

Results of the confocal microscopy (Figure 2D) showed that all the cells treated with Ac3ManNAzOH lipid-loaded liposomes could generate fluorescence on the cell membrane after treatment with DBCO-Cy5 compared with PBS as the negative control and the free AAM as the positive control. Cell labeling efficiencies were significantly improved by the long ester tail lipid loaded liposome. The C6 and C12 lipid loaded liposomes showed better fluorescence intensities than the C2 lipid-loaded liposomes, which indicated that long ester tails on C-1-OH could not only improve chemical stability of the sugar part but also enhance the labeling efficiency.

**SUMMARY AND CONCLUSION**

In summary, we developed an enhanced metabolic cell labeling strategy of a liposomal azido carbohydrate carrier by Ac3ManNAzOH lipids with C6 and C12 ester tails on the anomeric hydroxyl group. All the lipids with ester tails of different lengths could be delivered in liposome systems with good loading efficiency, and the metabolic cell labeling efficiencies maintained on MDA-MB-231 cells as AAM. The labeling efficiency seemed better after extending the length of the ester on anomeric carbon. This work may provide a promising cell labeling system based on metabolic oligosaccharide engineering via Cu-free click chemistry.

**EXPERIMENTAL SECTION**

**General Experimental Details.** All other reagents were used as obtained from commercial sources. Room temperature refers to ambient temperature. Temperatures of 0 °C were maintained using an ice–water bath. Thin-layer chromatography was performed using silica gel 60 with F254 indicator on glass plates (Merck). Flash chromatography was performed using Merck 40–63 μm silica gel. Solvent ratios for the purification of compounds by flash chromatography are reported as percent volume (v/v). Reactions were performed using oven-dried glassware apparatus under an atmosphere of nitrogen or argon with anhydrous solvents. Anhydrous dichloromethane (DCM), hexane, and ethyl acetate were
purified by passing them through alumina columns and kept anhydrous in molecular sieves. NMR spectroscopy was performed in deuterated solvents at 20 °C. Chemical shifts (δ) are given in parts per million (ppm) relative to TMS, and the solvent residual signal is used as a reference. Abbreviations for peak multiplicities are s (singlet), d (doublet), t (triplet), dt (doublet of triplets), m (multiplet), and br (broad). Mass spectra were measured using an electrospray ionization (ESI) mass spectrometer. Details for the spectrometers and other methods are given in the Supporting Information.

Synthesis of Ac4ManNAz (2, AAM). Azidoacetic acid was prepared by adding sodium azide (NaN3, 2.6 g, 40.0 mmol) to bromoacetic acid (2.78 g, 20.0 mmol) in deionized water (30 mL) and stirring at room temperature for 48 h. Thin-layer chromatography (TLC) analysis using detection by bromocresol green stain indicated that the reaction was complete. The solution was extracted by ethyl acetate and washed with 1 M HCl aq.; the organic layer was washed with saturated NaCl aq., and dried over Na2SO4. The solvent was removed to obtain yellow oil (1.4 g, 69%). The crude product could be used directly for the next step. Compound 1 was synthesized as follows: d-Mannosamine hydrochloride (1.5 g, 7.0 mmol) was added to azidoacetic acid (0.98 g, 9.7 mmol) from the previous step. Triethylamine (TEA, 2.5 mL, 17.0 mmol) was added and the reaction mixture was stirred for 5 min at room temperature. Then the solution was cooled to 0 °C and N-hydroxybenzotriazole (HOBt, 0.95 g, 7.1 mmol) was added, followed by addition of 1-[3-(dimethylamino) propyl]-3-ethylcarbodiimide hydrochloride (EDC, 2.68 g, 14.0 mmol). The reaction was allowed to warm to room temperature overnight, at which point TLC analysis with ceric ammonium molybdate (CAM) stain indicates that the reaction is complete. The solution was concentrated to obtain crude 1 and then purified by silica gel chromatography with DCM-methanol (9:1, v/v) to colorless semisolid (3.1 g, 84%) which was acetylated directly. To a suspension of 1 (0.9 g, 3.4 mmol) in acetic anhydride (15 mL) was added anhydrous NaOAc (0.31 g, 3.8 mmol) and the mixture stirred at 140 °C for 10 h. The solution was resuspended in DCM and washed with saturated NaHCO3 aq. and saturated NaCl aq. The organic

Figure 2. (A) Flow cytometry analysis of the cellular internalization of the liposomes after 2 and 12 h incubation with the liposome and free C2 lipid (AAM). (B) SDS-PAGE analysis of azide groups in glycoproteins of MDA-MB-231 cells in vitro after 2 and 12 h incubation with the liposomes compared to free C2 lipid (AAM). The gel was detected under 365 nm UV directly after DBCO-Cy5 incubation for another 1 h. The Coomassie stain showed the total amount of protein. (C) SDS-PAGE analysis of azide groups in glycoprotein of MDA-MB-231 cells in vitro after 2 and 12 h incubation with free C2 lipid and C2 liposome. The gel was detected under 365 nm UV directly after DBCO-Cy5 incubation for another 1 h. The Coomassie stain showed the total amount of protein. (D) Confocal microscopy images of MDA-MB-231 cells incubated with 10 μM of Ac4ManNAzOH-lipid-loaded liposomes and free AAM for 12 h at 37 °C, followed by labeling with DBCO-Cy5 for another 1 h. Cells treated with PBS and labeled with DBCO-Cy5 were used as the control. The cell nucleus was stained with Hoechst and the membrane was stained with cell mask orange.
Phase was dried over Na₂SO₄, filtered, and concentrated. The crude material was then purified by silica gel chromatography, eluting with hexane-ethyl acetate (2:1, v/v) to obtain a yellow white solid (0.6 g, 41.0%, 1/1 α/β isomers). ¹H NMR (500 MHz, CDCl₃) δ 6.67 (d, J = 9.0 Hz, 1H), 6.60 (d, J = 9.3 Hz, 1H), 6.06 (s, 1H), 5.91 (s, 1H), 5.85 (dd, J = 10.2, 4.3 Hz, 1H), 5.23 (d, J = 10.1 Hz, 1H), 5.18 (t, J = 9.8 Hz, 1H), 5.07 (dd, J = 9.9, 3.9 Hz, 1H), 4.75 (dd, J = 9.1, 4.0, 1.7 Hz, 1H), 4.63 (ddd, J = 9.2, 4.3, 2.0 Hz, 1H), 4.26 (dd, J = 12.0, 7.4, 4.4 Hz, 2H), 4.16 (dd, J = 12.5, 2.4 Hz, 1H), 4.13 (d, J = 2.5 Hz, 2H), 4.10—4.09 (m, 2H), 4.06 (d, J = 16.7 Hz, 2H), 3.84 (dd, J = 9.7, 4.6, 2.5 Hz, 1H), 2.20 (s, 3H), 2.13 (d, J = 2.1 Hz, 9H), 2.08 (s, 6H), 2.02 (d, J = 2.3 Hz, 6H). ¹³C NMR (126 MHz, CDCl₃) δ 170.48, 170.12, 170.07, 169.55, 169.33, 168.32, 168.08, 167.29, 166.71, 91.31, 90.26, 73.38, 71.42, 70.26, 68.85, 65.13, 64.96, 61.78, 61.69, 52.60, 52.42, 49.72, 49.27, 20.85, 20.77, 20.75, 20.70, 20.66, 20.63, 20.59. ESI-HRMS (m/z) C₁₆H₂₃N₂O₁₀: calculated 430.1336; found: 430.1332 [M + Na]⁺.

Synthesis of Ac₅ManNAzOH (3). Ac₅ManNAz (2, 0.3 g, 0.7 mmol) and ammonium carbonate (0.074 g, 0.77 mmol) were dissolved in methanol (10 mL) and stirred at room temperature for 8 h. TLC analysis using detection by CAM indicated that the reaction was finished, the solvent was removed, and the crude product was purified by silica gel column chromatography with DCM-ethyl acetate (2:1, v/v) to yield a white solid (0.2 g, 73.6%, 5/1 α/β isomers). ¹H NMR (500 MHz, CDCl₃) δ 6.67 (m, 1H), 6.60 (m, 1H), 6.06 (m, 1H), 5.91 (m, 1H), 5.85 (m, 1H), 5.23 (m, 1H), 5.18 (m, 1H), 5.07 (m, 1H), 4.75 (m, 1H), 4.63 (m, 1H), 4.26 (m, 1H), 4.16 (m, 1H), 4.13 (m, 1H), 4.06 (dd, J = 10.1 Hz, 1H), 5.22 (t, J = 9.1 Hz, 1H), 4.61 (dd, J = 7.6, 4.1 Hz, 1H), 4.24 (dd, J = 12.1, 3.9 Hz, 1H), 4.13 (d, J = 8.0 Hz, 1H), 4.10 (s, 1H), 4.03 (d, J = 10.1 Hz, 2H), 2.42 (t, J = 7.5 Hz, 2H), 2.12 (s, 3H), 2.07 (s, 3H), 2.00 (s, 3H), 1.68—1.63 (m, 3H), 1.25 (d, J = 3.6 Hz, 16H), 0.88 (s, 4H). ¹³C NMR (126 MHz, CDCl₃) δ 170.91, 170.47, 170.06, 169.53, 166.63, 91.11, 77.27, 77.02, 76.76, 70.27, 68.93, 65.14, 61.77, 52.46, 49.31, 34.03, 31.91, 29.60, 24.66, 22.69, 20.59, 14.12. ESI-HRMS (m/z) C₂₀H₃₂N₄O₁₆: calculated 570.2901; found: 579.2872 [M + Na]⁺.
