Materials

All chemicals are purchased from MilliporeSigma (St. Louis, MO, USA) unless otherwise specified. Amino acids were purchased from Chem-Impex Inc. (Wood Dale, IL, USA). Dialysis membrane with a molecular-weight cut-off (MWCO) of 1 kDa was purchased from Repligen Corporation (Waltham, MA, USA). Anhydrous dimethylformamide (DMF) was treated with isocyanate beads (MilliporeSigma, St. Louis, MO, USA) to remove nucleophilic impurities, and stored in a glovebox. Anhydrous tetrahydrofuran (THF) and hexane was dried in a column using alumina. The monomer γ-chloropropyl-L-glutamate NCA was synthesized following literature procedures.¹

Instrumentation

¹H and ¹³C NMR spectra were obtained on a Varian U500 spectrometer in NMR laboratory, University of Illinois. The chemical shifts of the spectra were referenced to the solvent proton and recorded in ppm. Gel permeation chromatography (GPC) characterizations were carried out on an instrument equipped with an isocratic pump (1260 Infinity II, Agilent, Santa Clara, CA, USA), a multi-angle static light scattering (MALS) detector with the detection wavelength at 658 nm (DAWN HELOS-II, Wyatt Technology, Santa Barbara, CA, USA), and a differential refractometer (DRI) detector (Optilab T-rEX, Wyatt Technology, Santa Barbara, CA, USA). Separations were performed using serially connected size exclusion columns (three PLgel MIXED-B columns, 10 μm, 7.5 × 300 mm, Agilent, Santa Clara, CA, USA) using DMF containing 0.1 M LiBr at 40 °C as the mobile phase at a flow rate of 0.7 mL/min. The MALS detector was calibrated using pure toluene and can be used for the determination of the absolute molecular weights (MWs). All sample solutions were filtered using a 0.45 μm PTFE filter before injection. The $dn/dc$ value of each sample was calculated offline by using the internal calibration system processed by the ASTRA 7 software (version 7.1.3.15, Wyatt Technology, Santa Barbara, CA, USA) and was used to determine the MWs of polypeptides. Circular dichroism (CD) measurements were carried out on a JASCO J-815 CD spectrometer (JASCO, Easton, MD, USA). The mean residue molar ellipticity of each polypeptide was calculated on the basis of the measured apparent ellipticity by the following formulas: Ellipticity ([\(\theta\)] in deg cm² dmol⁻¹) = (milidegrees × mean residue molecular weight)/(path length in millimeters × concentration of polypeptide in mg/mL).²³ Helicity was calculated by the following equation: helicity = ($-\theta_{222}$ nm] + 3000)/39000 × 100%.⁴ Lyophilization was performed on a FreeZone lyophilizer (Labconco, Kansas City, MO, USA).

### Synthesis of triazole polypeptides

Triazole polypeptides were synthesized with the copper-catalyzed, Huisgen click reaction between azide-bearing polypeptides and alkyne-containing molecules. Generally, PAPLG (40 mg, 0.19 mmol of side-chain azide groups), \(N,N,N',N''\)-pentamethyldiethylenetriamine (PMDETA) (19.7 \(\mu\)L, 0.09 mmol) and alkyne-containing molecules (0.28 mmol, 1.5 equiv.) were dissolved in DMF (1 mL) in a glovebox. CuBr (2.7 mg, 0.02 mmol) was then added into the solution and the mixture was stirred at room temperature for 24 h. The reaction was then quenched by exposing to air. The resulting solution was dialyzed in a dialysis membrane (MWCO = 1 kDa) against EDTA solution for 1 h to remove the copper salts, and then against DI water for 6 h (water changed every hour). The final triazole polypeptides were obtained after lyophilization (65-82% yield).
